CentrAlign Founding Engineer Problem Statement

AI Employee / Autonomous Company Operator

Company tasks are spread across websites, desktop apps, documents, and internal systems.

People must find information, follow procedures, and manually complete and check the work.

Short requests often leave the required steps and company context unstated.

AI-generated answers alone do not complete these tasks.

We want to reduce this manual effort across different kinds of business work.

We are building an **AI operator that turns a company request into completed work.**

It should use company context to identify the right sources, procedures, and permitted actions.

It should operate browsers, desktop apps, and files using existing tools wherever possible.

It should verify the outcome, return useful evidence, and ask for help when needed.

The goal is **reliable completion of varied company tasks with minimal human supervision.**

Think of the direction as something like a desktop AI assistant, but substantially more autonomous and focused on **completing outcomes rather than simply assisting the user.**

Your Task

Come up with **your vision of the solution and build a working prototype/proof of concept.**

The problem statement is intentionally open ended.

We are **not prescribing**:

- The architecture
- Models

- Agent framework
- Programming language
- Interface
- Computer-use technology
- Planning architecture
- Memory implementation
- Exact workflow

We want to understand **how you interpret the problem and how you would approach solving it.**

Your solution does not need to solve every possible company task.

A narrow system that genuinely demonstrates autonomy is considerably more valuable than a broad prototype that only simulates it.

We Would Like to See

Your submission should ideally demonstrate:

- Understanding a user's intended outcome.
- Determining what needs to be done.
- Planning the required actions.
- Selecting appropriate tools.
- Executing actions.
- Observing what happened.
- Determining the next action based on the result.
- Recovering from failures where reasonable.
- Maintaining relevant state/context.
- Asking for human input or approval when required.
- Verifying that the requested outcome was actually completed.
- Returning evidence or a useful summary of what happened.

The core loop we are interested in is roughly:

Goal → Understand → Plan → Execute → Observe → Adapt → Verify → Complete

You are encouraged to interpret this differently if you believe there is a better approach.
